Neutralizing Antibodies for Pre- and Post-Exposure Prophylaxis

Section last reviewed and 5/23/2022
Last literature search conducted 4/30/2022

Resources:
- CDC: SARS-CoV-2 variants
- FDA: Qualifications for SARS-CoV-2 exposure
- FDA: EUA for Evusheld™ (tixagevimab co-packaged with cilgavimab)
- NIH: National Center for Advancing Translational Science

Recommendation 1 (UPDATED 5/23/2022): In moderately or severely immunocompromised individuals* at increased risk for inadequate immune response to COVID-19 vaccine or for persons whom COVID-19 vaccine is not recommended due to a documented serious adverse reaction to the vaccine, the IDSA guideline panel suggests pre-exposure prophylaxis with tixagevimab/cilgavimab rather than no tixagevimab/cilgavimab, when predominant regional variants are susceptible to the agent (Conditional recommendation, Low certainty of evidence)

Remarks:
- Dosing for tixagevimab/cilgavimab is 300 mg of tixagevimab and 300 mg of cilgavimab administered as two separate consecutive intramuscular injections once.

*See Figure 1 below

Real-time weekly updates to regional circulating variant proportions can be found here: CDC COVID Data Tracker: Variant Proportions
Figure 1. FDA EUA criteria for the use of tixagevimab/cilgavimab for pre-exposure prophylaxis of COVID-19 in moderately or severely immunocompromised patients

According to the FDA Emergency Use Authorization of Evusheld, medical conditions or treatments that may result in moderate to severe immune compromise include but are not limited to:

- Active treatment for solid tumor and hematologic malignancies
- Receipt of solid-organ transplant and taking immunosuppressive therapy
- Receipt of chimeric antigen receptor (CAR)-T-cell or hematopoietic stem cell transplant (within 2 years of transplantation or taking immunosuppression therapy)
- Moderate or severe primary immunodeficiency (e.g., DiGeorge syndrome, Wiskott-Aldrich syndrome)
- Advanced or untreated HIV infection (people with HIV and CD4 cell counts <200 mm$^3$, history of an AIDS-defining illness without immune reconstitution, or clinical manifestations of symptomatic HIV)
- Active treatment with high-dose corticosteroids (i.e., $\geq 20$ mg prednisone or equivalent per day when administered for $\geq 2$ weeks), alkylating agents, antimetabolites, transplant-related immunosuppressive drugs, chancer chemotherapeutic agents classified as severely immunosuppressive, tumor-necrosis (TNF) blockers, and other biologic agents that are immunosuppressive or immunomodulatory (e.g., B-cell depleting agents)

Reference

Figure 2. FDA EUA criteria for the use of tixagevimab/cilgavimab for pre-exposure prophylaxis of COVID-19

This EUA for the use of the unapproved products tixagevimab and cilgavimab for pre-exposure prophylaxis in adults and pediatric individuals (12 years of age and older weighing at least 40 kg) who are:

- Not currently infected with SARS-CoV-2 and who have not had a known recent exposure to an individual infected with SARS-CoV-2 AND:
  - have moderate to severe immune compromise due to a medical condition OR receipt of immunosuppressive medications or treatments AND may not mount an adequate immune response to COVID-19 vaccination OR
  - For whom vaccination with any available COVID-19 vaccine, according to the approved or authorized schedule, is not recommended due to a history of severe adverse reaction (e.g., severe allergic reaction) to a COVID-19 vaccine(s) and/or a COVID-19 vaccine component(s).

Reference

Recommendation 2 (UPDATED 5/23/2022): In persons exposed to COVID-19 who are at high risk of progression to severe COVID-19, the IDSA guideline panel suggests against post-exposure casirivimab/imdevimab, unless predominant regional variants are susceptible to the agent. (Conditional recommendation, Low certainty of evidence)

Why are neutralizing antibodies considered for prophylaxis?

Neutralizing antibodies directed at the receptor-binding domain of SARS-CoV-2 spike protein have been evaluated as prophylactic agents for COVID-19. In animal models there is evidence that antibody therapy may more rapidly reduce viral load in the upper and lower airways of infected animals resulting in reduced viral-induced pathology, demonstrating in vivo prophylactic and treatment efficacy [1, 2]. Additionally, antibody mediated enhancement of disease, a theoretical adverse effect of neutralizing antibody prophylaxis, has not been detected in animal models or seen in clinical studies [2]. In a large, randomized study of unvaccinated nursing home patients and staff where there was at least one confirmed case of COVID-19 at the facility, a single dose of bamlanivimab appeared to significantly reduce the incidence of “mild or worse” COVID-19 among the nursing home residents [3].

Potential advantages of neutralizing antibodies include the ability to standardize the amount of neutralizing activity and the possibility of conferring protection more rapidly than with vaccine-induced immune responses (which generally take several weeks).

As the pandemic progressed, new SARS CoV-2 variants emerged with reduced neutralizing susceptibility to various anti-SARS-CoV-2 monoclonal antibodies (mAb) in assays performed using infectious (also referred to as authentic) and pseudotyped viruses. For example, the first two authorized mAb combinations, bamlanivimab/etesevimab and casirivimab/imdevimab, have been found to be largely inactive against the Omicron BA.1 and BA.2 variants.

In a meta-analysis published as a preprint, the combination of tixagevimab/cilgavimab displayed a median 86-fold (IQR: 27-151) reduction in activity against Omicron BA.1 in 15 studies, and a median 5.4-fold (IQR: 3.7-6.9) reduction in activity against Omicron BA.2 in six studies.

As a result of the reduced susceptibility of tixagevimab/cilgavimab to the BA.1 variant, the FDA recommended on February 24, 2022, that the dosage for each mAb in this combination be increased from 150 mg to 300 mg intramuscularly.
Summary of the evidence

Tixagevimab/cilgavimab

Our search identified one randomized controlled trial (RCT) reporting on pre-exposure prophylaxis (PrEP) with a single dose of intramuscular tixagevimab/cilgavimab administration in adults ≥18 years of age who are at increased risk of inadequate response to COVID-19 vaccination or SARS-CoV-2 infection [4, 5]. Patients included were those that were either age ≥60 years, immunocompromised, had severe renal or liver impairment, COPD, or those who had an increased risk of exposure including those working in healthcare or living in congregate living settings. All participants had a negative SARS-CoV-2 serology test result at screening, had no history of SARS-CoV-2 infection, and had not received vaccine or biologic indicated for prevention of SARS-CoV-2 or COVID-19. Study participants received a single combined 300 mg intramuscular dose of the combination of tixagevimab (150 mg)/cilgavimab (150 mg).

Casirivimab/imdevimab

Our search identified one RCT reporting on post-exposure prophylaxis (PEP) with neutralizing antibodies (combination of casirivimab/imdevimab) for patients exposed to COVID-19 who are at high risk of progression to severe disease [6].

One RCT reported on 1,505 persons testing negative for SARS-CoV-2 infection (by reverse-transcriptase-quantitative polymerase-chain-reaction assay [RT-qPCR]) within 96 hours following household contact with a diagnosis of SARS-CoV-2 infection [6]. Of those included in the trial, 30.5% participants were categorized as having a high risk of COVID-19 (e.g., ≥65 years of age, body mass index [BMI] ≥35, chronic kidney disease, etc.). Participants in the treatment group received a total dose of 1200 mg of casirivimab/imdevimab subcutaneously.

Benefits

Tixagevimab/cilgavimab

PrEP with tixagevimab/cilgavimab appears to have little or no effect on mortality through a median of 6 months (risk ratio [RR]: 0.50; 95% confidence interval [CI]: 0.13, 2.0; absolute risk reduction: 1 fewer per 1,000 [from 2 fewer to 2 more]; moderate certainty of evidence [CoE]). Symptomatic COVID-19 infection within six months after administration was reduced in those who received tixagevimab/cilgavimab compared to placebo (RR: 0.18; 95% CI: 0.09, 0.35; moderate CoE).

Casirivimab/imdevimab

Persons receiving post-exposure prophylaxis with casirivimab/imdevimab reduced symptomatic SARS-CoV-2 infection from 7.8% to 1.5% (RR: 0.19; 95% CI: 0.10, 0.35; moderate
CoE). Of the 70 persons who developed symptomatic infection, those who received casirivimab/imdevimab rather than placebo experienced a shorter duration of symptoms (mean difference [MD]: -2.0 weeks; 95% CI: -2.91, -1.09; low CoE).

**Harms**

**Tixagevimab/cilgavimab**

Serious adverse events were not meaningfully different in those that received PrEP with tixagevimab/cilgavimab compared to placebo (RR: 1.09; 95% CI: 0.67, 1.78; moderate CoE).

**Casirivimab/imdevimab**

Serious treatment-emergent adverse events may be less frequent among persons receiving casirivimab/imdevimab compared to those receiving placebo; however, this may not be meaningfully different from those receiving placebo (RR: 0.66; 95% CI: 0.30, 1.47; low CoE).

**Other considerations**

**Tixagevimab/cilgavimab**

The panel agreed that the overall certainty of evidence for PrEP with tixagevimab/cilgavimab was low due to concerns with the generalizability of the trial population to the FDA-authorized indications (e.g., immunocompromised persons) and low number of events (fragility of results). The panel noted concerns with feasibility at different centers given the large number of potentially eligible individuals and supply constraints.

**Casirivimab/imdevimab**

The panel agreed that the overall certainty of evidence for post-exposure prophylaxis with casirivimab/imdevimab was low due to low number of events (fragility of results). The panel notes some indirectness between the trial participants (30.5% with any high-risk factor for COVID) and the current approved indications for post-exposure prophylaxis within the EUA.

**Conclusions and research needs for this recommendation**

**Tixagevimab/cilgavimab**

The guideline panel suggests PrEP with tixagevimab/cilgavimab in moderately or severely immunocompromised individuals at increased risk for inadequate immune response to COVID-19 vaccine or for whom COVID-19 vaccine is not recommended due to documented severe reactions to the COVID-19 vaccine. Data on the efficacy of pre-exposure prophylaxis specifically in immunocompromised individuals who have received COVID-19 vaccines are needed.
Casirivimab/imdevimab

The guideline panel suggests against post-exposure casirivimab/imdevimab, unless predominant regional variants are susceptible to the agent.

GRADE Working Group grades of evidence
High certainty: We are very confident that the true effect lies close to that of the estimate of the effect
Moderate certainty: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different
Low certainty: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect
Very low certainty: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Risk of bias: Study limitations
Inconsistency: Unexplained heterogeneity across study findings
Indirectness: Applicability or generalizability to the research question
Imprecision: The confidence in the estimate of an effect to support a particular decision
Publication bias: Selective publication of studies

NB: Certainty ratings may be derived from evidence that includes pre-print articles, which have not been peer reviewed or published.
CI: Confidence interval; HR: Hazard ratio; RR: Risk ratio

Explanations
Possible misclassification bias due to unequal rate of drop-outs after unblinding.
2. 2 deaths in the control arm were attributed to COVID-19.
3. Trial population indirect to the population indicated within the FDA EUA (e.g., immunocompromised).
4. Small number of events; fragility present.

**GRADE Working Group grades of evidence**

- **High certainty:** We are very confident that the true effect lies close to that of the estimate of the effect
- **Moderate certainty:** We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different
- **Low certainty:** Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect
- **Very low certainty:** We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of the effect

**Risk of bias:** Study limitations

**Inconsistency:** Unexplained heterogeneity across study findings

**Indirectness:** Applicability or generalizability to the research question

**Imprecision:** The confidence in the estimate of an effect to support a particular decision

**Publication bias:** Selective publication of studies
NB: Certainty ratings may be derived from evidence that includes pre-print articles, which have not been peer reviewed or published.

CI: Confidence interval; RR: Risk ratio; MD: Mean difference

Explanations
a. Small number of events; fragility present
b. COVID-19 related hospitalizations is a surrogate for ICU admission, mechanical ventilation and death. Not rated down.
c. 95% CI cannot exclude meaningful harm
d. Serious treatment emergent adverse events reported for entire study population (including symptomatic and asymptomatic) and may not be generalizable to seronegative population.
