Antimicrobial Prophylaxis for Adult Patients With Cancer-Related Immunosuppression: ASCO and IDSA Clinical Practice Guideline Update

ABSTRACT

Purpose
To provide an updated joint ASCO/Infectious Diseases Society of America (IDSA) guideline on antimicrobial prophylaxis for adult patients with immunosuppression associated with cancer and its treatment.

Methods
ASCO and IDSA convened an update Expert Panel and conducted a systematic review of relevant studies from May 2011 to November 2016. The guideline recommendations were based on the review of evidence by the Expert Panel.

Results
Six new or updated meta-analyses and six new primary studies were added to the updated systematic review.

Recommendations
Antibacterial and antifungal prophylaxis is recommended for patients who are at high risk of infection, including patients who are expected to have profound, protracted neutropenia, which is defined as < 100 neutrophils/µL for > 7 days or other risk factors. Herpes simplex virus–seropositive patients undergoing allogeneic hematopoietic stem-cell transplantation or leukemia induction therapy should receive nucleoside analog-based antiviral prophylaxis, such as acyclovir. Pneumocystis jirovecii prophylaxis is recommended for patients receiving chemotherapy regimens that are associated with a > 3.5% risk for pneumonia as a result of this organism (eg, those with ≥ 20 mg prednisone equivalents daily for ≥ 1 month or on the basis of purine analog usage). Treatment with a nucleoside reverse transcription inhibitor (eg, entecavir or tenofovir) is recommended for patients at high risk of hepatitis B virus reactivation. Recommendations for vaccination and avoidance of prolonged contact with environments that have high concentrations of airborne fungal spores are also provided within the updated guideline. Additional information is available at www.asco.org/supportive-care-guidelines.

INTRODUCTION

Patients undergoing cytotoxic chemotherapy and hematopoietic stem-cell transplantation (HSCT) are at risk for infection, particularly during the period of neutropenia. Neutrophils are critical for providing host defense against infection, particularly bacterial and fungal infection. The risk of infection increases with the depth and duration of neutropenia, with the greatest risk occurring in patients who experience profound, prolonged neutropenia after chemotherapy, which is most likely to occur in the period before engraftment during HSCT and after induction chemotherapy for acute leukemia. Fever can be an important indicator and is often the only sign or symptom of infection, although clinicians should also be mindful that severely or profoundly neutropenic patients may present with suspected infection in an afebrile state or even hypothermic. Prevention and appropriate management of febrile neutropenia (FN) is important because the rate of major complications (eg, hypotension, acute renal, respiratory, or heart failure) in the context of FN is approximately 25% to 30% and mortality up to 11%. In the setting of severe sepsis or septic shock, the hospital mortality rate may be as high as

Antimicrobial Prophylaxis for Adult Patients With Cancer-Related Immunosuppression: ASCO and IDSA Clinical Practice Guideline Update

Guideline Question
What antimicrobial prophylaxis is appropriate for immunosuppressed patients with cancer?

Target Population
Patients receiving treatment of cancer as inpatients or outpatients who are experiencing immune suppression or increased susceptibility to infection.

Target Audience
Oncologists, infectious disease specialists, emergency medicine physicians, nurses, and advanced practice providers who may treat patients with immunosuppression resulting from cancer treatment.

Methods
An Expert Panel convened to update clinical practice guideline recommendations on the basis of a systematic review of the medical literature.

Key Recommendations
A summary of antimicrobial prophylaxis recommendations can be found here and in Table 1.

Antimicrobial prophylaxis:

Recommendation 1.1: Risk of febrile neutropenia (FN) should be systematically assessed (in consultation with infectious disease specialists as needed), including patient-, cancer-, and treatment-related factors (Table 2). (Type: evidence-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: strong.)

Recommendation 1.2: Antibiotic prophylaxis with a fluoroquinolone is recommended for patients who are at high risk for FN or profound, protracted neutropenia (eg, most patients with acute myeloid leukemia/myelodysplastic syndromes (AML/MDS) or hematopoietic stem-cell transplantation (HSCT) treated with myeloablative conditioning regimens). Antibiotic prophylaxis is not routinely recommended for patients with solid tumors. (Type: evidence-based; benefits outweigh harms; Evidence quality: high; Strength of recommendation: moderate.)

Recommendation 2.1: Antifungal prophylaxis with an oral triazole or parenteral echinocandin is recommended for patients who are at risk for profound, protracted neutropenia, such as most patients with AML/MDS or HSCT. Antifungal prophylaxis is not routinely recommended for patients with solid tumors. Additional distinctions between recommendations for invasive candidiasis and invasive mold infection are provided within the full text of the guideline. (Type: evidence-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: moderate.)

Recommendation 2.2: Prophylaxis is recommended, eg, trimethoprim-sulfamethoxazole (TMP-SMX), for patients receiving chemotherapy regimens associated with > 3.5% risk for pneumonia from Pneumocystis jirovecii (eg, those with ≥ 20 mg prednisone equivalents daily for ≥ 1 month or those on the basis of purine analogs). (Type: evidence-based; benefits outweigh harms; Evidence quality: high; Strength of recommendation: strong.)

Recommendation 3.1: Herpes simplex virus–seropositive patients undergoing allogeneic HSCT or leukemia induction therapy should receive prophylaxis with a nucleoside analog (eg, acyclovir). (Type: evidence-based; benefits outweigh harms; Evidence quality: high; Strength of recommendation: moderate.)

Recommendation 3.2: Treatment with a nucleoside reverse transcription inhibitor (eg, entecavir or tenofovir) is recommended for patients who are at high risk of hepatitis B virus reactivation. (Type: consensus-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: moderate.)

Recommendation 3.3: Yearly influenza vaccination with inactivated vaccine is recommended for all patients receiving chemotherapy for malignancy and all family and household contacts and health care providers. (Type: consensus-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: moderate.)

Recommendation 3.4: The Expert Panel also supports other vaccination recommendations for immunosuppressed adult oncology patients that are contained within the IDSA guideline for vaccination of the immunosuppressed host.16,62

(continued on following page)
Additional recommended precautions

Recommendation 4.1: All health care workers should comply with hand hygiene and respiratory hygiene/cough etiquette guidelines to reduce the risk for aerosol- and direct or indirect contact–based transmission of pathogenic microorganisms in the health care setting. (Type: consensus-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: strong.)

Recommendation 4.2: Outpatients with neutropenia from cancer therapy should avoid prolonged contact with environments that have high concentrations of airborne fungal spores (eg, construction and demolition sites, intensive exposure to soil through gardening or digging, or household renovation). (Type: consensus-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: strong.)

Please see the complete guideline document that follows this summary for further details and qualifying statements to the recommendations.

ASCO believes that cancer clinical trials are vital to inform medical decisions and improve cancer care, and that all patients should have the opportunity to participate.

Additional Resources: More information, including a Data Supplement with additional evidence tables, a Methodology Supplement with information about evidence quality and strength of recommendations, slide sets, and clinical tools and resources, is available at www.asco.org/supportive-care-guidelines. Patient information is available at www.cancer.net

GUIDELINE QUESTIONS

This clinical practice guideline addresses the following clinical questions:

1. Does antibacterial prophylaxis with a fluoroquinolone, compared with placebo, no intervention, or another class of antibiotic reduce the incidence of and mortality related to FN?

2. Does antifungal (antiyeast or antimold) prophylaxis with an oral triazole or parenteral echinocandin, compared with no prophylaxis or another treatment option, reduce the incidence of and mortality related to FN?
3. Is other prophylaxis, eg, antiviral, more effective than placebo/no treatment for higher-risk immunosuppressed patients with cancer?

4. Are precautions such as neutropenic diet, etc., more effective than no intervention for prophylaxis of infection in afebrile neutropenic outpatients?

lists the definitions for fever and neutropenia that were used by the Expert Panel.

**Box 1. Definitions of fever and neutropenia**

Fever in neutropenic patients is defined as a single oral temperature of ≥ 38.3°C (101°F) or a temperature of ≥ 38.0°C (100.4°F) sustained over a 1-hour period. Neutropenia is defined as an absolute neutrophil count < 1,000/µL (equivalent to < 1.0 × 10⁹/L), severe neutropenia as absolute neutrophil count < 500/µL (equivalent to < 0.5 × 10⁹/L), and profound neutropenia as < 100/µL (equivalent to < 0.1 × 10⁹/L). The period of neutropenia is considered protracted if it lasts for ≥ 7 days.

*Grade 3 and 4 neutropenia. Treatment included colony-stimulating factors and antimicrobial prophylaxis. Rate of neutropenia varied by chemotherapy regimen.*
The ASCO Expert Panel and guidelines staff work with co-chairs to keep abreast of any substantive updates to the guideline. On the basis of formal review of the emerging literature, ASCO determines the need to update. The Methodology Supplement (available at www.asco.org/supportive-care-guidelines) provides additional information about the ASCO Signals approach to updating.

This is the most recent information as of the publication date. Visit the ASCO Guidelines Web site at www.asco.org/supportive-care-guidelines to submit new evidence.

Guideline Disclaimer. The Clinical Practice Guidelines and other guidance published herein are provided by the American Society of Clinical Oncology, Inc. (ASCO) to assist providers in clinical decision-making. The information herein should not be relied upon as being complete or accurate, nor should it be considered as inclusive of all proper treatments or methods of care or as a statement of the standard of care. With the rapid development of scientific knowledge, new evidence may emerge between the time information is developed and when it is published or read. The information is not continually updated and may not reflect the most recent evidence. The information addresses only the topics specifically identified therein and is not applicable to other interventions, diseases, or stages of diseases. This information does not mandate any particular course of medical care. Further, the information is not intended to substitute for the independent professional judgment of the treating provider, as the information does not account for individual variation among patients. Recommendations reflect high, moderate, or low confidence that the recommendation reflects the net effect of a given course of action. The use of words like “must,” “must not,” “should,” and “should not” indicates that a course of action is recommended or not recommended for either most or many patients, but there is latitude for the treating physician to select other courses of action in individual cases. In all cases, the selected course of action should be considered by the treating provider in the context of treating the individual patient. Use of the information is voluntary. ASCO provides this information on an “as is” basis and makes no warranty, express or implied, regarding the information. ASCO specifically disclaims any warranties of merchantability or fitness for a particular use or purpose. ASCO assumes no responsibility for any injury or damage to persons or property arising out of or related to any use of this information, or for any errors or omissions.

Guideline and Conflicts of Interest. The Expert Panel was assembled in accordance with ASCO’s Conflict of Interest Policy Implementation for Clinical Practice Guidelines (“Policy,” found at http://www.asco.org/rwc). All members of the Expert Panel completed ASCO’s disclosure form, which requires disclosure of financial and other interests, including relationships with commercial entities that are reasonably likely to experience direct regulatory or commercial impact as a result of promulgation of the guideline. Categories for disclosure include employment; leadership; stock or other ownership; honoraria, consulting or advisory role; speaker’s bureau; research funding; patents, royalties, other intellectual property; expert testimony; travel, accommodations, expenses; and other relationships. In accordance with the Policy, the majority of the members of the Expert Panel did not disclose any relationships constituting a conflict under the Policy.

Table 1 provides a summary of antimicrobial prophylaxis recommendations.

**RECOMMENDATIONS**

**CLINICAL QUESTION 1**

**Antibacterial Prophylaxis.** Does antibacterial prophylaxis with a fluoroquinolone, compared with placebo, no intervention, or another class of antibiotic, reduce the incidence of and mortality as a result of febrile episodes in patients with cancer?

**Recommendation 1.1.** Risk of FN should be systematically assessed (in consultation with infectious disease specialists as needed), including patient-, cancer-, and treatment-related factors (Table 2). (Type: evidence-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: strong.)

**Recommendation 1.2.** Antibiotic prophylaxis with a fluoroquinolone is recommended for patients who are at high risk for FN or profound, protracted neutropenia—for example, patients with acute myeloid leukemia/myelodysplastic syndromes (AML/MDS) or HSCT treated with myeloablative conditioning regimens. Antibiotic prophylaxis is not routinely recommended for patients with solid tumors. (Type: evidence-based; benefits outweigh harms; Evidence quality: high; Strength of recommendation: moderate.)

**Qualifying Statements.**

- Antibacterial prophylaxis is recommended during the expected period of neutropenia in patients who meet the proposed criteria for use.
- Antibacterial prophylaxis is not recommended for patients who are at low risk of profound, protracted neutropenia.
- Antibacterial and antifungal prophylaxis would generally not be indicated when CSF prophylaxis effectively reduces the depth and duration of neutropenia.
- Fluoroquinolone-based antibacterial prophylaxis may have limited utility among matched-related HSCT on the basis of reduced-intensity conditioning regimens.
- Fluoroquinolone resistance rates among community-acquired Enterobacteriaceae isolates in the United States have risen from < 1% to as high as 30% during the decade from the late 1990s to 2009.41 GI colonization by fluoroquinolone-resistant—and extended-spectrum β-lactamase–positive—gram-negative bacilli has been a risk factor for bacteremic events in the setting of GI mucositis, and fluoroquinolone resistance may result in inappropriate initial empirical antibacterial therapy and increased all-cause mortality.42,43 A threshold prevalence of fluoroquinolone resistance among *Escherichia coli* isolates above which the protective efficacy of fluoroquinolone prophylaxis may be limited has not been defined.44
- The activity of fluoroquinolone prophylaxis on the intestinal microbiome is to select not only for fluoroquinolone-resistant, gram-negative bacilli, but also for *Clostridium difficile* and enterococci.45 Clinicians must be mindful of the clinical syndromes associated with these pathogens and appropriately tailor their therapeutic approaches.

**Literature review update.** An updated systematic review of antibiotic prophylaxis for bacterial infections in febrile neutropenic patients after chemotherapy included 109 studies that compared antibiotic prophylaxis options with each other or placebo or no intervention.46 A quality assessment conducted by the review authors concluded that the quality of the outcome data was generally moderate to high. Detailed characteristics of included trials are included in the full systematic review publication.46

In the subgroup of patients who were at higher risk as defined earlier, quinolone prophylaxis resulted in significant reductions in all-cause mortality (relative risk [RR], 0.57; 95% CI, 0.4 to 0.82) and febrile patients/episodes (RR, 0.79; 95% CI, 0.69 to 0.9). In the lower-risk subgroup of patients with solid tumors, quinolone prophylaxis also resulted in significant reductions in all-cause
mortality (RR, 0.48; CI 95%, 0.26 to 0.88) and febrile patients/episodes (RR, 0.57; 95% CI, 0.43 to 0.76). The number-needed-to-treat to prevent one death from any cause was 29 for the high-risk group compared with 63 for the lower-risk group, and baseline risk of all-cause mortality was approximately 2.5 times higher in the former group. Infection-related mortality was also significantly improved with quinolone prophylaxis in the high-risk group (RR, 0.53; 95% CI, 0.32 to 0.86), whereas this outcome was uncertain in the solid tumors group because of a low number of events. Across subgroups, more adverse events, mostly including nausea and diarrhea, were reported in the treatment group.

**Clinical interpretation.** Fluoroquinolones were recommended over trimethoprim-sulfamethoxazole (TMP-SMX) in the previous version of this guideline because the former drug class results in fewer adverse events that lead to discontinuation of treatment. Update panel members continue to be supportive of this recommendation on the basis of updated results from the review described above. Two main studies provided the majority of the data for that analysis, and no large studies of similar significance have been found in this guideline update. Whereas a significant reduction in FN incidence and mortality was found in both high- and low-risk populations outlined in Clinical Question 1, the benefits (eg, infection prevention and decreased all-cause mortality) did not sufficiently outweigh the harms (emergence of resistance, \textit{C. difficile} infection, antibiotic-associated adverse effects) in patients with solid tumors/lymphoma to justify the recommendation of fluoroquinolone prophylaxis for all patients in this group. The higher incidence of all-cause mortality and the lower number needed to treat led the panel to conclude that the benefits of routine fluoroquinolone prophylaxis would outweigh the harms for high-risk patients who were undergoing treatment for acute leukemia or stem-cell transplantation. Fluoroquinolone prophylaxis may also be recommended for some patients with solid tumors or lymphoma who are expected to experience profound neutropenia for at least 7 days and for whom granulocyte CSF is not being prescribed. Notwithstanding, the US Food and Drug Administration, on July 26, 2016, issued an updated warning to clinicians that advised that fluoroquinolone antibacterial agents have been associated with disabling and potentially permanent adverse effects involving tendons, muscles, joints, peripheral nerves, and the CNS, and that these agents should be reserved for patients with serious bacterial infections for whom the benefits outweigh the harms or for less serious bacterial infections for which there may be no other treatment options. In the context of this guideline, clinicians should consider the desired fluoroquinolone-driven treatment outcome, the subgroup of neutropenic patients in which the treatment outcome is desired, and these updated warnings.

For patients who are intolerant or allergic to fluoroquinolones, cefpodoxime has been used as an alternative agent for neutropenic prophylaxis.49

**CLINICAL QUESTION 2**

**Antifungal Prophylaxis.** Does antifungal prophylaxis with an oral triazole or parenteral echinocandin, compared with no prophylaxis or another treatment option, reduce the incidence of and mortality as a result of febrile episodes in patients with cancer?

**Recommendation 2.1.** Antifungal prophylaxis with an oral triazole or parenteral echinocandin is recommended for patients who are at risk for profound, protracted neutropenia, such as most patients with AML/MDS or undergoing HSCT. Prophylaxis is not routinely recommended for patients with solid tumors. (Type: evidence-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: moderate.)

**Qualifying Statements.**

- Antifungal prophylaxis is recommended during the expected period of neutropenia in those patients who are anticipated to have profound, protracted neutropenia and grade III or IV mucositis where the risk for invasive candidiasis is high.
- Clinicians should be able to differentiate the risks for invasive candidiasis from the risks for invasive mold infection. Fluconazole, which is active against yeast but not mold, has for the most part been effective in reducing the risks of the former, but not the latter. Examples of mold-active agents include echinocandins and other azole antifungals, such as posaconazole, voriconazole, or isavuconazole.
- A mold-active triazole is recommended where the risk of invasive aspergillosis is > 6%, such as in patients with AML/MDS during the neutropenic period associated with chemotherapy.
- Invasive mold infection risk is now observed to be greater in late-stage postallogeic SCT, and a mold-active antifungal should be considered in this context (eg, posaconazole) and/or in the context of GVHD.14,50-53
- Antifungal prophylaxis is not recommended for patients who are at low risk of profound, protracted neutropenia.
- Antibacterial and antifungal prophylaxis would generally not be indicated when CSF prophylaxis effectively reduces the depth and duration of neutropenia.5

**Recommendation 2.2.** Prophylaxis is recommended, eg, TMP-SMX—for patients receiving chemotherapy regimens associated with > 3.5% risk for pneumonia from \textit{Pneumocystis jirovecii} (eg, those with ≥ 20 mg prednisone equivalents daily for ≥ 1 month or those on the basis of purine analogs. (Type: evidence-based; benefits outweigh harms; Evidence quality: high; Strength of recommendation: strong.)

**Qualifying Statement.**

- Alternatives such as dapsone, aerosolized pentamidine, or atovaquone are options for individuals who may be hypersensitive to sulfonamides or unable to tolerate TMP-SMX for other reasons.

**Literature review update and analysis.** An updated Cochrane review, which included 29 trials of antifungal prophylaxis and three trials of empirically administered antifungals in patients with cancer with neutropenia found no significant difference between antifungals and placebo or no treatment of all-cause mortality at approximately 3 months (RR, 0.94; 95% CI, 0.81 to 1.09); however, there was a significant effect for death related to fungal infection (RR, 0.52; 95% CI, 0.38 to 0.71) and invasive infections (RR, 0.50; 95% CI, 0.39 to 0.64). Results of a subgroup analysis of recipients of allogeneic HSCT demonstrated no significant difference in all-cause mortality (RR, 0.71; 95% CI, 0.49 to 1.04) using follow-up numbers from Gotzsche et al.44 Baseline rates of fungal infections in the control groups were 7.6% (all patients receiving HSCT and chemotherapy) and 20% (patients
receiving HSCT only). In a subgroup analysis, Robenshtok et al did not find a significant difference in all-cause mortality for autologous and allogeneic HSCT combined (RR, 0.67; 95% CI, 0.42 to 1.09) or patients with acute leukemia (RR, 0.88; 95% CI, 0.74 to 1.06); however, a difference was found in fungal-related mortality for allogeneic HSCT (RR, 0.52; 95% CI, 0.27 to 0.99).

Evidence is emerging about the risk of infection with newer cancer therapy options. A retrospective review of the medical records of 740 patients with melanoma who received immune checkpoint blockers found that serious infection occurred in 54 patients (7.3%). The main risk factors for infection were the receipt of corticosteroids and/or infliximab. The Expert Panel also noted that, according to manufacturers, serious Pneumocystis jirovecii pneumonia infections occurred in 0.6% of 317 patients who were treated with copanlisib monotherapy and in < 1% of patients who were treated with idelalisib.

Clinical interpretation. The previous version of this guideline recommended antifungal prophylaxis when there is a substantial risk for invasive fungal infection. This revised guideline reaffirms this recommendation, including antifungal prophylaxis with an oral triazole or parenteral echinocandin in the case of a population level risk of Candida infection > 10% and a mold-active triazole when the population level risk of aspergillosis is > 6%. The panel recognized that significant heterogeneity exists between patient groups that are dependent on disease and treatment-related variation but concluded that this risk level would generally apply to patients undergoing induction therapy for acute leukemia or HSCT because of their higher likelihood of experiencing a profound, protracted period of neutropenia. The panel considered the potential reduction in fungal-related mortality when reaching consensus on this recommendation. The recommendation for PIP prophylaxis remains unchanged from the previous version of this guideline. The Expert Panel will consider prophylaxis for patients undergoing therapy with phosphatidylinositol-3-kinase inhibitors (eg, idelalisib or copanlisib) in the next iteration of this guideline, pending additional supporting evidence. In addition, the panel noted that PIP prophylaxis may be considered in the setting of prolonged corticosteroid use (> 20 mg/d for > 4 weeks) to treat immune-related adverse events associated with checkpoint inhibitors and other immunotherapies, pending additional supporting evidence.

CLINICAL QUESTION 3

Antiviral Prophylaxis. Does antiviral prophylaxis reduce the incidence of immunosuppression-related viral infections in patients with cancer compared with no prophylaxis or another treatment option?

Recommendation 3.1. Herpes simplex virus-seropositive patients undergoing allogeneic HSCT or leukemia induction therapy should receive antiviral prophylaxis with a nucleoside analog (eg, acyclovir). (Type: evidence-based; benefits outweigh harms; Evidence quality: high; Strength of recommendation: strong.)

Recommendation 3.2. Treatment with a nucleoside reverse transcription inhibitor (eg, entecavir or tenofovir) is recommended for patients at high risk of hepatitis B virus reactivation. (Type: consensus-based; benefits outweigh harms; Evidence quality: intermediate; Strength of recommendation: moderate.)
Recommendation 4.2. Outpatients with neutropenia from cancer therapy should avoid prolonged contact with environments that have high concentrations of airborne fungal spores (eg, construction and demolition sites, intensive exposure to soil through gardening or digging, or household renovation). (Type: evidence-based; benefits outweigh harms; Evidence quality: strong; Strength of recommendation: strong.)

Literature review update and analysis. According to the previous version of this guideline, recommendations for hand hygiene reflect the endorsement of the practices deemed prudent by the US Centers for Disease Control and Prevention. Recommendation 4.2 is based on retrospective reports and the panel opinion regarding prudent practices. Studies included in the previous version of this review include high-efficiency particulate air-filtered protected environments, respiratory masks, footwear exchange, and dietary interventions did not demonstrate any significant differences in outcomes, although protected environments may play a limited role in the prevention of airborne acquisition of infections, such as invasive mold, in the event that the patient remains in the protected environment and does not import an infection from previous exposure. Included in this update is a new meta-analysis of neutropenic diets—that is, diets that generally include cooked foods and restrict raw fruit, vegetables, fish meat, and soft cheese, which did not show a protective benefit with intervention.

Clinical interpretation. The Expert Panel continues to endorse the ASCO recommendations from the previous version of this guideline, including recommendations from the US Centers for Disease Control and Prevention for hand hygiene and the prevention of infection in outpatient settings and recommendations against interventions, such as footwear exchange, protected environments, respiratory or surgical masks, neutropenic diet, or nutritional supplements, for which evidence of clinical benefit is lacking.

DISCUSSION

This updated guideline includes the latest evidence on prophylaxis for immunosuppressed adult patients undergoing treatment of malignancy. Updated systematic reviews and meta-analyses and new single studies did not include any new information that would alter the recommendations for antibiotic or antifungal prophylaxis included in the previous version of this review. Prophylaxis recommendations are stratified by high- and low-risk categories, and antibiotic and antifungal prophylaxis is recommended for higher-risk patients on the basis of patient- and treatment-related factors. For this updated version of the guideline, antiviral prophylaxis recommendations are also included and good practice recommendations related to vaccinations are outlined. This guideline does not provide a detailed discussion of monotherapies, combination therapies, and multitagent therapies. For this information, the reader is referred to the Surviving Sepsis Campaign guideline. In addition, this guideline does not provide recommendations for specific agents and dosing schedules as a result of our inability to continuously update these guidelines as new agents are approved or as new evidence is published.

With the addition of few new studies to the evidence base, the Expert Panel continued to endorse previous recommendations with minor modifications noted within the guideline text; ASCO will continue to monitor the literature for new information and update this guideline at regular intervals.

PATIENT AND CLINICIAN COMMUNICATION

Recommendations throughout this document are aimed at a target audience of oncologists, infectious disease specialists, emergency medicine physicians, nurses, and advanced practice providers. The patient representative included in our Expert Panel highlighted the importance of communication between these clinicians and both inpatients and outpatients with regard to education about safety practices, what patients need to be aware of to communicate with clinicians, and expectations of patient/caregiver responsibilities once discharged. Across the recommendations contained within this guideline, the patient representative highlighted that infection prophylaxis information should be provided to patients and caregivers, including details from the recommendations that are related to hand hygiene, respiratory hygiene/cough etiquette, and avoidance of prolonged contact with environments that have high concentrations of airborne fungal spores. Patients frequently have questions about neutropenic diets or nutritional supplements; therefore, recommendations related to these topics should be included in patient materials.

HEALTH DISPARITIES

Although ASCO clinical practice guidelines represent expert recommendations on best practices in disease management to provide the highest level of cancer care, it is important to note that many patients have limited access to medical care. Racial and ethnic disparities in health care contribute significantly to this problem in the United States. Patients with cancer who are members of racial or ethnic minorities suffer disproportionately from comorbidities, experience more substantial obstacles to receiving care, are more likely to be uninsured, and are at greater risk of receiving poor-quality care than other Americans. Many other patients lack access to care because of their geographic location and distance from appropriate treatment facilities. Awareness of these disparities in access to care should be considered in the context of this clinical practice guideline, and health care providers should strive to deliver the highest level of cancer care to these vulnerable populations.

MULTIPLE CHRONIC CONDITIONS

Creating evidence-based recommendations to inform the treatment of patients with additional chronic conditions, a situation in which the patient may have two or more such conditions—referred to as multiple chronic conditions (MCCs)—is challenging. Patients with MCCs are a complex and heterogeneous population, which makes it difficult to account for all possible permutations to develop specific recommendations for care. In addition, the best
available evidence for treating index conditions, such as cancer, is often from clinical trials whose study selection criteria may exclude these patients to avoid potential interaction effects or confounding of results associated with MCCs. As a result, the reliability of outcome data from these studies may be limited, thereby creating constraints for expert groups to make recommendations for care in this heterogeneous patient population.

As many patients for whom guideline recommendations apply present with MCCs, any treatment plan must take into account the complexity and uncertainty created by the presence of MCCs and highlight the importance of shared decision making regarding guideline use and implementation. Therefore, in consideration of the recommended care for the target index condition, clinicians should review all other chronic conditions that are present in the patient and take into account those conditions when formulating the treatment and follow-up plan.

In light of the above considerations, practice guidelines should provide information on how to apply the recommendations for patients with MCCs, perhaps as a qualifying statement for recommended care. This may mean that some or all of the recommended care options are modified or not applied, as determined by best practice in consideration of any MCC.

**COST IMPLICATIONS**

The burden of a cancer diagnosis extends beyond the physical and psychological impacts of the disease; the social and financial impact of cancer, cancer treatment, and supportive care on the patient and family can be profound for patients worldwide. Out-of-pocket expenses incurred by patients in accessing care can range widely and can affect patients’ financial well-being significantly. In particular, for patients with cancer who experience extreme financial toxicity, such as bankruptcy, these financial effects can be associated with increased mortality. The financial consequences associated with diagnostic and treatment choices for patients with cancer with FN rarely are associated with significant costs; however, the cost implications of mismanagement of a patients with cancer with FN who subsequently requires intensive care or prolonged hospital stays can be substantial. Whereas discussions about the costs of cancer supportive care commonly focus on balancing the potential to save and extend lives with the costs to society or payers, the low cost of most interventions discussed in this guideline and their potential impact on infectious complications suggest that they have a favorable cost-benefit ratio even without formal evaluations.

**GUIDELINE IMPLEMENTATION**

ASCO guidelines are developed for implementation across health settings. Barriers to implementation include the need to increase awareness of the guideline recommendations among front-line practitioners and survivors of cancer and caregivers, and also to provide adequate services in the face of limited resources. The guideline Bottom Line Box was designed to facilitate implementation of recommendations. This guideline will be distributed widely through the ASCO Practice Guideline Implementation Network. ASCO guidelines are posted on the ASCO Web site and most often published in *Journal of Clinical Oncology* and *Journal of Oncology Practice.*

ASCO believes that cancer clinical trials are vital to inform medical decisions and improve cancer care, and that all patients should have the opportunity to participate.

**ADDITIONAL RESOURCES**

Submit new evidence or access more information, including a Data Supplement with additional evidence tables, a Methodology Supplement with information about evidence quality and strength of recommendations, slide sets, and clinical tools and resources, at www.asco.org/supportive-care-guidelines.
